## Mutational Analysis of the Antagonist-binding Site of the Histamine H<sub>1</sub> Receptor\*

(Received for publication, December 31, 1998, and in revised form, June 4, 1999)

Kerstin Wieland‡, Anton M. Ter Laak§, Martine J. Smit‡, Ronald Kühne§, Henk Timmerman‡, and Rob Leurs‡¶

From the ‡Leiden/Amsterdam Center for Drug Research, Department of Pharmacochimistry, Division of Medicinal Chemistry, Faculty of Chemistry, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, the Netherlands and the §Institute for Molecular Pharmacology, Biocomputing/Molecular Modelling Group, Alfred Kowalke Strasse 4, D-10315 Berlin, Germany

We combined in a previously derived three-dimensional model of the histamine H<sub>1</sub> receptor (Ter Laak, A. M., Timmerman, H., Leurs, H., Nederkoorn, P. H. J., Smit, M. J., and Donne-Op den Kelder, G. M. (1995) *J. Comp. Aid. Mol. Design.* 9, 319–330) a pharmacophore for the H<sub>1</sub> antagonist binding site (Ter Laak, A. M., Venhorst, J., Timmerman, H., and Donne-Op de Kelder, G. M. (1994) *J. Med. Chem.* 38, 3351–3360) with the known interacting amino acid residue Asp<sup>116</sup> (in transmembrane domain III) of the H<sub>1</sub> receptor and verified the predicted receptor-ligand interactions by site-directed mutagenesis. This resulted in the identification of the aromatic amino acids Trp<sup>167</sup>, Phe<sup>433</sup>, and Phe<sup>436</sup> in transmembrane domains IV and VI of the H<sub>1</sub> receptor as probable interaction points for the *trans*-aromatic ring of the H<sub>1</sub> antagonists. Subsequently, a specific interaction of carboxylate moieties of two therapeutically important, zwitterionic H<sub>1</sub> antagonists with Lys<sup>200</sup> in transmembrane domain V was predicted. A Lys<sup>200</sup> → Ala mutation results in a 50- (acrivastine) to 8-fold (d-cetirizine) loss of affinity of these zwitterionic antagonists. In contrast, the affinities of structural analogs of acrivastine and cetirizine lacking the carboxylate group, triprolidine and meclozine, respectively, are unaffected by the Lys<sup>200</sup> → Ala mutation. These data strongly suggest that Lys<sup>200</sup>, unique for the H<sub>1</sub> receptor, acts as a specific anchor point for these “second generation” H<sub>1</sub> antagonists.

Since the initial discovery of the role of histamine in allergic conditions (1) serious efforts have been made to develop drugs that inhibit the actions of histamine. Already in 1933, Fourneau and Bovet (2) reported the first “antihistamine” piperoxan. Following this finding many potent H<sub>1</sub> antagonists that can be considered as variations of diaryl-substituted ethylamines (e.g. diphenhydramine and mepyramine) have been developed (for review see Ref. 3). These “first generation” H<sub>1</sub> antagonists are quite effective in humans in allergic rhinitis and urticaria, but because of central nervous system penetration and central H<sub>1</sub> receptor blockade their clinical use is hampered by sedative side effects (3–5). A “second generation” of non-sedative H<sub>1</sub> antagonists (e.g. astemizole, acrivastine, cetirizine, loratidine, and terfenadine) has recently been developed (for review see Ref. 3). Their altered pharmacokinetics result in

good clinical effectiveness combined with a strongly reduced sedative potential (3–5).

The development of H<sub>1</sub> antagonists has so far been directed by traditional medicinal chemistry (3). With the availability of the genetic information of the histamine H<sub>1</sub> receptor (6), the rationalization of drug-protein interaction has become a major challenge for this therapeutically important class of drugs. Like all aminergic G-protein coupled receptors (GPCR),<sup>1</sup> the H<sub>1</sub> receptor contains an aspartate residue (Asp<sup>116</sup>) in transmembrane domain (TM) III (6), that is involved in the binding of the protonated amine function found in both agonists and antagonists structures (7, 8). Mutagenesis studies have furthermore shown that the imidazole ring of histamine is accommodated by Lys<sup>200</sup> and Asn<sup>207</sup> in TM V (9, 10).

In view of the low sequence similarity between GPCRs and bacteriorhodopsin (BR) much controversy exists on the validity of models derived for GPCRs based on the homology with BR (11–13). Nevertheless, despite the speculative nature of BR-derived GPCR models they have been quite helpful in understanding and predicting drug-receptor interactions for a variety of receptors (see e.g. Refs. 14–16). Previously, we also developed a three-dimensional computer model of the histamine H<sub>1</sub> receptor based on the homology with BR, incorporating the results obtained from mutagenesis studies on the agonist binding site (17). In the present study this computer model of the H<sub>1</sub> receptor was combined with a pharmacophoric model of the H<sub>1</sub> antagonistic binding site (18). This ligand-based model for the H<sub>1</sub> antagonistic binding site is based upon an interaction of the protonated amine function of various first generation, semi-rigid H<sub>1</sub> antagonists with an aspartate residue (Asp<sup>116</sup> in the guinea pig H<sub>1</sub> receptor) (18) and precisely positions the *cis*- and *trans*-aromatic rings of the H<sub>1</sub> antagonists relative to the C<sub>α</sub> and C<sub>β</sub> carbon atoms of this aspartate residue. Combining the three-dimensional receptor model and the ligand-based pharmacophoric model of the H<sub>1</sub> antagonist binding site resulted in the prediction of interactions of aromatic amino acids in TM IV and VI with the H<sub>1</sub> antagonists. Subsequently, we experimentally confirmed the involvement of these predicted amino acids in the binding of the H<sub>1</sub> antagonist [<sup>3</sup>H]mepyramine by site-directed mutagenesis. Moreover, on the basis of the three-dimensional model of the antagonist-receptor complex, a specific interaction of carboxylate moieties of therapeutically important, second generation zwitterionic H<sub>1</sub> antagonists (acrivastine and cetirizine) with Lys<sup>200</sup> in TM V was predicted and experimentally verified.

<sup>1</sup> The abbreviations used are: GPCR, G-protein coupled receptor; BR, bacteriorhodopsin; TM, transmembrane domain.

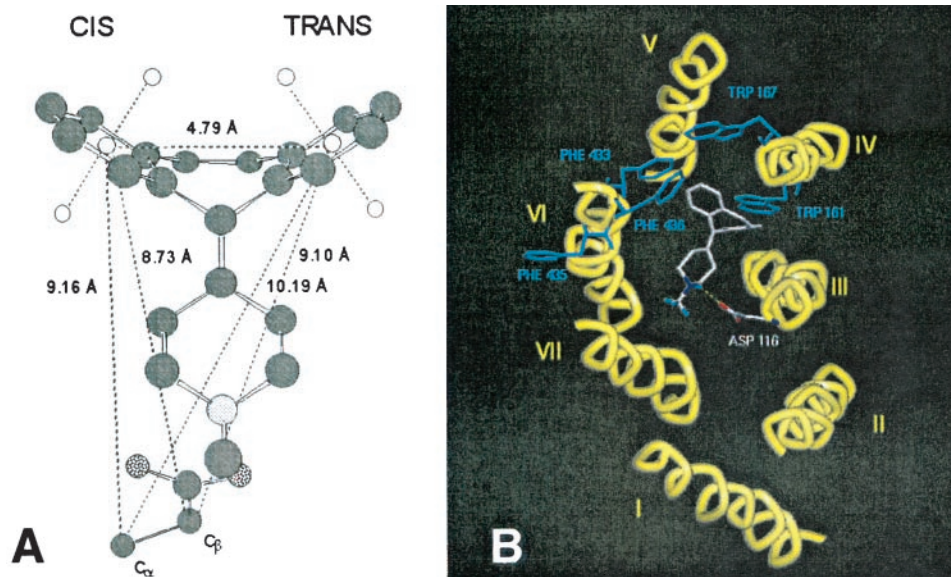

FIG. 1. *A*, the  $H_1$  antagonist pharmacophore of Ter Laak *et al.* (18) describing the position of the *cis*- and *trans*-aromatic rings of  $H_1$  antagonists with respect to the  $C_\alpha$  and  $C_\beta$  carbon atoms of a putative aspartate residue. *B*, the  $H_1$  antagonist pharmacophore was docked into the  $H_1$  receptor model based on BR (17). A view from the extracellular side shows the orientation of cyproheptadine between the TMs (yellow) and the ionic hydrogen bond interaction with Asp<sup>116</sup> in TM III. The *trans*-aromatic ring of cyproheptadine is in the proximity of Phe<sup>433</sup>, Phe<sup>436</sup> (TM VI), and Trp<sup>167</sup> (TM IV), and the *cis*-aromatic ring is near Trp<sup>161</sup> (TM IV). Two other aromatic residues that were mutated in this study (Phe<sup>435</sup> and Trp<sup>174</sup>) are not in the proximity of the  $H_1$  antagonist in this model. Phe<sup>435</sup> points toward the membrane, and Trp<sup>174</sup> is not shown because in this alignment the residue lies outside the TM region.

#### EXPERIMENTAL PROCEDURES

**Materials**—Bovine serum albumin, DEAE-dextran, polyethyleneimine, and triprolidine hydrochloride were obtained from Sigma. The mouse anti-FLAG M2 monoclonal antibody was obtained from International Biotechnology Inc. The fluorescein isothiocyanate-conjugated rabbit-anti-mouse secondary antibody was supplied by Dakopatts AB (Stockholm, Sweden). [<sup>3</sup>H]Mepyramine (28 Ci/mmol) was obtained from Amersham Pharmacia Biotech. Gifts of acrivastine (The Wellcome Foundation Ltd., London, United Kingdom), d-cetirizine hydrochloride, meclozine hydrochloride (UCB, Braine-l'Alleud, Belgium), and mianserin hydrochloride (Organon NV, Oss, the Netherlands) are gratefully acknowledged.

**Prediction of Ligand-Receptor Interactions**— $H_1$  antagonists were docked in the previously described three-dimensional receptor model of the guinea pig  $H_1$  receptor (17), using the rigid  $H_1$  antagonist pharmacophoric model of Ter Laak *et al.* (18). This model describes the three-dimensional topology of the *cis*- and *trans*-aromatic rings of cyproheptadine with respect to the positions of the  $C_\alpha$  and  $C_\beta$  carbon atoms of an putative Asp residue from the receptor (see Fig. 1A). The  $C_\alpha$  and  $C_\beta$  carbon atoms of the pharmacophore replaced the corresponding atoms of Asp<sup>116</sup> in the receptor model. Rotation was carried out along the  $C_\alpha$ - $C_\beta$  bond until cyproheptadine was positioned in the receptor in an energetically favorable orientation. The structure of the zwitterionic compounds acrivastine and d-cetirizine were built and optimized with Chem-X and subsequently docked into the  $H_1$  receptor model onto the cyproheptadine template as described previously (18). Subsequently, all freely rotatable bonds in Lys<sup>200</sup> and in the side chains of the zwitterionic  $H_1$  antagonist were taken into account in an extensive conformational analysis (MacroModel/AMBER force field (19)).

**Site-directed Mutagenesis**—The guinea pig  $H_1$  receptor cDNA was subcloned in the pALTER vector (Promega), and point mutations were introduced according to the manufacturer's protocol. The wild type and mutant receptors were epitope-tagged with an N-terminal FLAG peptide (DYKDDDD) after modification of the cDNA sequence with polymerase chain reaction. In our initial binding studies (see Fig. 2) non-tagged receptors were used. The cDNA sequences were verified using the dideoxy chain termination method with the Sequenase kit (U. S. Biochemical Corp.).

**Cell Culture and Transfection**—COS-7 and HEK-293 cells were grown at 37 °C in a humidified atmosphere with 5% CO<sub>2</sub> in Dulbecco's modified Eagle's medium, containing 2 mM L-glutamine, 50 IU/ml penicillin, 50 µg/ml streptomycin, and 5 or 10% (v/v) fetal calf serum, respectively. Cells were transiently transfected with pcDNA3, containing the wild type or mutant  $H_1$  receptor cDNA, using DEAE-dextran (COS-7 cells) or calcium phosphate (HEK-293 cells).

**Histamine  $H_1$  Receptor Binding Studies**—Transfected cells were harvested after 48 h, homogenized in ice-cold 50 mM Na<sub>2</sub>/potassium phosphate buffer (pH 7.4) and used for radioligand binding studies. Cell homogenates (40–50 µg of protein) were incubated for 30 min at 25 °C in 50 mM Na<sub>2</sub>/potassium phosphate buffer (pH 7.4) in 400 µl with the indicated concentrations of [<sup>3</sup>H]mepyramine. The nonspecific binding was defined in the presence of 1 µM mianserin. In displacement studies, cell homogenates were incubated with 1 nM [<sup>3</sup>H]mepyramine and increasing concentrations of competing ligands. The incubations were stopped by rapid dilution with 3 ml of ice-cold 50 mM Na<sub>2</sub>/potassium phosphate buffer (pH 7.4). The bound radioactivity was separated by filtration through Whatman GF/C filters that had been treated with 0.3% polyethyleneimine. Filters were washed twice with 3 ml of buffer, and radioactivity retained on the filters was measured by liquid scintillation counting. The binding data were evaluated by a nonlinear, least squares curve fitting procedure. Protein levels were determined according to Bradford (20), using bovine serum albumin as standard.

**[<sup>3</sup>H]Inositol Phosphate Production**—HEK-293 cells were seeded in 12-well plates and 24 h after transfection labeled overnight in inositol-free culture medium supplemented with 2 µCi/ml myo-[2-<sup>3</sup>H]inositol. Cells were stimulated for 1 h at 37 °C with Dulbecco's modified Eagle's medium containing 25 mM Hepes (pH 7.4), 20 mM LiCl, and histamine. The incubation was stopped by aspiration of the culture medium and the addition of cold CHCl<sub>3</sub>/methanol (1:2 v/v). After extraction with water, [<sup>3</sup>H]inositol phosphates were isolated by anion exchange chromatography (21).

**Immunofluorescence**—Transfected COS-7 cells were grown on glass coverslips and after 48 h fixed with 4% paraformaldehyde/phosphate-buffered saline for 30 min at room temperature and blocked in phosphate-buffered saline/0.1% bovine serum albumin for 1 h at room temperature. Antigen detection was performed as described (22).

#### RESULTS

**Prediction of Ligand-Receptor Interaction Based on Receptor Modelling**—The  $H_1$  antagonist pharmacophoric model of Ter Laak *et al.* (18) represents low energy conformations of several potent and rigid  $H_1$  antagonists (cyproheptadine, phenindamine, triprolidine, epinastine, mequitazine, and mianserin) and is able to discriminate between the stereochemically different *cis*- and *trans*-aromatic rings of these  $H_1$  antagonists (Fig. 1A). To predict amino acid residues involved in the ligand-binding site of these  $H_1$  antagonists the cyproheptadine pharmacophore was docked into the previously derived model of the  $H_1$

FIG. 2. Effects of the mutation of aromatic amino acids in TM IV and VI on the binding of the  $H_1$  antagonist [ $^3H$ ]mepyramine to wild type, Phe $^{435}$  → Ala, Trp $^{174}$  → Ala, Trp $^{167}$  → Ala, Phe $^{436}$  → Ala, Trp $^{161}$  → Ala, and Phe $^{433}$  → Ala  $H_1$  receptor after transient expression in COS-7 cells. The data shown are from a representative example out of at least three independent experiments.

receptor. After rotation over the  $C_\alpha$ - $C_\beta$  bond of Asp $^{116}$  and energy optimizations, a single energetically favorable orientation was found for the  $H_1$  antagonist. In this orientation the aromatic rings of the  $H_1$  antagonist were located in the receptor-binding pocket between the TMs III, IV, V, and VI (Fig. 1B). The aromatic rings of cyproheptadine were surrounded by several aromatic amino acids. In the  $H_1$  receptor model, the *cis*-ring of cyproheptadine is located within 5 Å of a tryptophane in TM IV (Trp $^{161}$ ), whereas the *trans*-aromatic ring is close to two phenylalanines in TM VI (Phe $^{433}$  and Phe $^{436}$ ) and Trp $^{167}$  in TM IV (Fig. 1B). All these predicted residues are conserved in all the reported  $H_1$  receptor sequences (23–29).

**Verification of the  $H_1$  Antagonist-binding Site by Site-directed Mutagenesis**—To verify the interaction of  $H_1$  antagonists with the predicted amino acids these residues were initially mutated to alanines. Moreover, two related amino acids (Trp $^{174}$  in TM IV and Phe $^{435}$  in TM VI) that are also conserved in all the reported  $H_1$  receptor sequences (23–29) but not predicted by the GPCR model were also mutated. In the derived model Phe $^{435}$  points into the phospholipid bilayer (Fig. 1B), and Trp $^{174}$  is located just outside TM IV.

The mutant receptors were expressed transiently in COS-7 cells and analyzed by [ $^3H$ ]mepyramine saturation binding studies. Expression of the wild type  $H_1$  receptor in COS-7 cells resulted in a high affinity binding site for [ $^3H$ ]mepyramine ( $K_D = 0.7 \pm 0.1$  nM, mean  $\pm$  S.E.,  $n = 3$ ) (Fig. 2). Mutation of the tryptophane residues Trp $^{161}$ , Trp $^{167}$ , and Trp $^{174}$  in TM IV to alanine residues resulted in distinct effects on the [ $^3H$ ]mepyramine binding to the mutant receptors (Fig. 2). The introduction of the Trp $^{174}$  → Ala mutation did not reduce the affinity of [ $^3H$ ]mepyramine (Fig. 2;  $K_D = 3.6 \pm 0.6$  nM, mean  $\pm$  S.E.,  $n = 3$ ) dramatically. In contrast, for the Trp $^{167}$ Ala receptor the affinity for the  $H_1$  antagonist was reduced more than 10-fold (Fig. 2;  $K_D > 15$  nM,  $n = 3$ ), whereas cells expressing the Trp $^{161}$  → Ala receptor did not show binding of [ $^3H$ ]mepyramine (Fig. 2) significantly higher than binding to mock-transfected COS-7 cells (15–50 fmol/mg protein; data not shown). Similar findings were obtained with the three Phe-Ala mutations in TM VI. The Phe $^{435}$ Ala receptor mutant still bound [ $^3H$ ]mepyramine with high affinity (Fig. 2;  $K_D = 1.3 \pm 0.2$  nM, mean  $\pm$  S.E.,  $n = 3$ ), whereas for the other two mutants a reduced (Phe $^{436}$  → Ala receptor,  $K_D > 15$  nM,  $n = 3$ ) or totally impaired (Phe $^{433}$  → Ala receptor) [ $^3H$ ]mepyramine binding was observed (Fig. 2).

To verify protein expression of the two receptor mutants that did not show detectable [ $^3H$ ]mepyramine binding (Trp $^{161}$  → Ala and Phe $^{433}$  → Ala), a FLAG epitope was introduced at the N terminus of the wild type and mutant  $H_1$  receptor proteins.

Using confocal laser microscopy we identified specific, anti-FLAG immunofluorescence in the plasma membrane of COS-7 cells expressing the epitope-tagged wild type and the Phe $^{433}$  → Ala  $H_1$  receptor (Fig. 3). For the Trp $^{161}$  → Ala  $H_1$  receptor, the anti-FLAG immunofluorescence was mainly found inside the cell, indicating perturbed receptor expression.

Based on the observed loss of antagonist affinity upon mutation of Trp $^{167}$ , Phe $^{433}$ , and Phe $^{436}$ , we considered these amino acids as likely candidates for the hypothesized interaction with the aromatic rings of the  $H_1$  antagonist. To investigate the role of Trp $^{161}$ , Trp $^{167}$ , Phe $^{433}$ , and Phe $^{436}$  in more detail, we changed the tryptophane residues in TM IV to methionine and phenylalanine (Trp $^{161}$  → Met, Trp $^{161}$  → Phe, Trp $^{167}$  → Met, and Trp $^{167}$  → Phe) and the phenylalanine residues in TM 6 to methionine (Phe $^{433}$  → Met and Phe $^{436}$  → Met). The mutant receptors were epitope-tagged, expressed in COS-7 cells, and evaluated for [ $^3H$ ]mepyramine binding. In contrast to the Trp $^{161}$  → Ala receptor mutant, the Trp $^{161}$  → Met and Trp $^{161}$  → Phe receptor mutants bound [ $^3H$ ]mepyramine with high affinity (Table I). Yet the number of binding sites for the Trp $^{161}$  → Phe receptor mutant was considerably lower compared with the wild type and the Trp $^{161}$  → Met receptor mutant (Table I). As found for the Trp $^{167}$  → Ala receptor mutant, mutation of Trp $^{167}$  to Met or Phe resulted in strongly reduced affinity for [ $^3H$ ]mepyramine (Table I). In contrast, mutating Phe $^{433}$  and Phe $^{436}$  to Met allowed [ $^3H$ ]mepyramine binding with high affinity (Table I).

The affinity of the Trp $^{161}$  → Met and Trp $^{161}$  → Phe mutant receptors for histamine was not changed (Table I), whereas a small to major reduction of the agonist affinity was observed for the Phe $^{433}$  → Met and Phe $^{436}$  → Met receptor mutants (Table I). Because of the lack of saturable [ $^3H$ ]mepyramine binding, the agonist affinity could not be determined for the other mutants.

**Histamine-induced [ $^3H$ ]Inositol Phosphate Accumulation after Stimulation of Wild Type and Mutant  $H_1$  Receptors**—To test the functionality of the mutant receptors, we initially performed [ $^3H$ ]inositol phosphate accumulation experiments in transfected COS-7 cells. However, in mock-transfected COS-7 cells histamine increased basal [ $^3H$ ]inositol phosphate accumulation, suggesting the presence of an endogenously expressed  $H_1$  receptor.<sup>2</sup> In mock-transfected HEK-293 cells histamine did not stimulate the [ $^3H$ ]inositol phosphate accumulation (Fig. 4), whereas after overexpression of the epitope-tagged wild type  $H_1$  receptor protein ( $7.1 \pm 1.0$  pmol/mg protein, mean  $\pm$  S.E.,  $n = 3$ ) histamine (100  $\mu$ M) stimulated the [ $^3H$ ]inositol phosphate accumulation 5.9  $\pm$  0.4-fold (mean  $\pm$  S.E.,  $n = 3$ ) over basal levels (Fig. 4). Evaluation of the various receptor mutants showed that the Trp $^{161}$  → Met, Phe $^{433}$  → Ala, Phe $^{433}$  → Met, Phe $^{436}$  → Ala, and Phe $^{436}$  → Met mutant receptors stimulated the [ $^3H$ ]inositol phosphate accumulation as the wild type  $H_1$  receptor (Fig. 4). Similar  $EC_{50}$  values for histamine were observed for the wild type receptor and the Trp $^{161}$  → Met, Trp $^{161}$  → Phe, and Phe $^{433}$  → Ala receptors, whereas the Phe $^{433}$  → Met, Phe $^{436}$  → Ala, and Phe $^{436}$  → Met mutant receptors were stimulated less effectively by histamine (Table I). The expression levels of the mutant receptors in HEK-293 cells ranged from 2.4 (Phe $^{436}$  → Ala) to 10.6 pmol/mg protein (Trp $^{161}$  → Met). For the Phe $^{433}$  → Ala mutant no radioligand binding was found. As expected by the perturbed membrane expression, the Trp $^{161}$  → Ala receptor mutant did not respond to histamine (Fig. 4). As found for the expression in COS-7 cells, the Trp $^{161}$  → Phe was expressed at relatively low levels in HEK-293 cells ( $0.3 \pm 0.1$

<sup>2</sup> K. Wieland, H. Timmerman, and R. Leurs, unpublished observations.

FIG. 3. **Localization of epitope-tagged wild type (WT) and mutant  $H_1$  receptors, transiently expressed in COS-7 cells.** Transfected COS-7 cells were grown on glass coverslips and after 48 h fixed with 4% paraformaldehyde. Immunofluorescence was detected with the mouse anti-FLAG M2 antibody and a fluorescein isothiocyanate-conjugated secondary rabbit anti-mouse antibody.

TABLE I  
Effects of point mutations in TM 1V and V1 of the histamine  $H_1$  receptor on ligand binding and signal transduction

Receptors were expressed in COS-7 cells or HEK-293 cells and used 48 h after transfection for radioligand binding studies and the accumulation of [ $^3$ H]inositol phosphates, respectively. Data were calculated as the means  $\pm$  S.E. from at least three independent experiments. ND indicates that the value was not determined.

Receptor	$K_D$ [ $^3$ H]mepyramine	$H_1$ receptor density	$K_i$ histamine	$EC_{50}$ histamine	Basal stimulation
	nM	pmol/mg protein	$\mu$ M	$\mu$ M	fold

<sup>b</sup> Positive anti-FLAG immunofluorescence signals in the membrane.

FIG. 4. **Basal (open bars) and histamine (100  $\mu$ M) (closed bars) induced production of [ $^3$ H]inositol phosphates by wild type and mutant  $H_1$  receptors expressed in [ $^3$ H]inositol prelabeled HEK-293 cells.** The data shown are the means  $\pm$  S.E. of at least three independent experiments.

pmol/mg protein, means  $\pm$  S.E.,  $n = 3$ ). Despite its low expression level a significant stimulation (Fig. 4) of the mutant receptor by histamine was observed with comparable potency as the wild type receptor (Table I). For the various mutations of Trp<sup>167</sup> only the Trp<sup>167</sup>  $\rightarrow$  Phe mutation resulted in a mutant receptor that could be activated by histamine, although with a very low efficacy (Fig. 4 and Table I). Because of the lack of saturable binding in the [ $^3$ H]mepyramine binding studies, the expression levels of these mutant receptors could not be estimated.

**Predicted Interaction of the Zwitterionic  $H_1$  Antagonists Acrivastine and Cetirizine with Lys<sup>200</sup>**—To investigate whether the acidic moiety of the non-sedative, zwitterionic  $H_1$  antagonist acrivastine specifically interacts with the  $H_1$  receptor protein,

this ligand was docked into the  $H_1$  receptor model on top of the template cyproheptadine. Visual inspection of the resulting ligand-receptor complex suggested a possible interaction with Lys<sup>200</sup> in TM V. Following this observation a conformational analysis, giving rotational freedom to Lys<sup>200</sup> and the carboxylate group of the  $H_1$  antagonist, indeed predicted an interaction between the positively charged Lys<sup>200</sup> and the carboxylate group (Fig. 5A). In the case of d-cetirizine, the carboxylate group is attached to the basic nitrogen via a long ether chain. Docking cetirizine in the  $H_1$  receptor model indicated that the carboxylate of d-cetirizine reaches the proximity of Lys<sup>200</sup>, although the calculated N-O distance of 3.57 Å is somewhat large for a strong (ionic) hydrogen bond interaction (Fig. 5B).

**Interaction of  $H_1$  Antagonists with Lys<sup>200</sup> in TM V**—To verify the predicted interaction of Lys<sup>200</sup> with the carboxylate group of acrivastine, we mutated the basic lysine to alanine and methionine to disrupt the potential ionic interaction with the  $H_1$  antagonist. We also mutated Lys<sup>200</sup> to an arginine residue, because this basic amino acid should be able to interact with the carboxylate group of acrivastine. Previously, we showed that Lys<sup>200</sup> in TM V specifically interacts with some classes of  $H_1$  agonists (including histamine) but not with the prototypic  $H_1$  antagonists [ $^3$ H]mepyramine and d- and l-chlorpheniramine (10). Moreover, also the Lys<sup>200</sup>  $\rightarrow$  Arg and the Lys<sup>200</sup>  $\rightarrow$  Met mutations allowed high affinity [ $^3$ H]mepyramine binding after expression in COS-7 cells and similar to the Lys<sup>200</sup>  $\rightarrow$  Ala mutant (10) showed a slightly altered affinity for histamine (Table II). Functional studies in HEK-293 cells indicated that cells transiently transfected with the mutant receptors all responded to histamine with the accumulation of [ $^3$ H]inositol phosphates, although the  $EC_{50}$  values were higher than found for the wild type receptor (Table II). Displacement of the binding of [ $^3$ H]mepyramine to the Lys<sup>200</sup>  $\rightarrow$  Ala, Lys<sup>200</sup>  $\rightarrow$  Arg, and Lys<sup>200</sup>  $\rightarrow$  Met receptor mutants indicated a specific interaction

FIG. 5. Zwitterionic  $H_1$  antagonists acrivastine (A) and d-cetirizine (B) docked into the  $H_1$  receptor model. A, acrivastine, which fits the cyproheptadine pharmacophore (Fig. 1A), makes an additional (ionic) hydrogen bond interaction with Lys<sup>200</sup> (TM V). B, d-cetirizine docked into the same  $H_1$  receptor model and presenting the carboxylate moiety near Lys<sup>200</sup>.

TABLE II  
Effects of mutation of Lys<sup>200</sup> of the histamine  $H_1$  receptor on ligand binding and signal transduction

Receptors were expressed in COS-7 cells or HEK-293 cells and used 48 h after transfection for radioligand binding studies and the accumulation of [<sup>3</sup>H]inositol phosphates, respectively. The wild type, Lys<sup>200</sup> → Ala, Lys<sup>200</sup> → Met, and Lys<sup>200</sup> → Arg were expressed in HEK-293 cells at receptor densities of respectively 7.1 ± 1.0, 13.6 ± 1.5, 7.2 ± 1.1, and 7.1 ± 0.4 pmol/mg protein. Data were calculated as the means ± S.E. from at least three independent experiments.

Receptor	$K_D$ [ <sup>3</sup> H]mepyramine	$H_1$ receptor density	$K_i$ histamine	EC <sub>50</sub> histamine	Basal stimulation	$K_i$ acrivastine
	nM	pmol/mg protein	μM	μM	fold	nM
wild type	0.7 ± 0.1	9.5 ± 4.2	76 ± 19	0.04 ± 0.02	5.9 ± 0.4	10 ± 3
Lys <sup>200</sup> → Ala	1.6 ± 0.2	17.1 ± 0.3	320 ± 22	2.3 ± 1.2	5.3 ± 0.5	548 ± 52
Lys <sup>200</sup> → Met	1.9 ± 0.2	17.3 ± 5.1	281 ± 18	1.7 ± 0.6	5.8 ± 0.6	534 ± 97
Lys <sup>200</sup> → Arg	5.7 ± 0.6	13.9 ± 4.7	182 ± 5	1.9 ± 0.8	7.4 ± 0.9	37 ± 11

of Lys<sup>200</sup> with acrivastine. The  $K_i$  value for acrivastine was increased more than 50-fold following the Lys<sup>200</sup> → Ala and Lys<sup>200</sup> → Met mutations (Fig. 6A and Table II). In contrast, acrivastine still showed high affinity for the Lys<sup>200</sup> → Arg receptor mutant (Fig. 6A and Table II). To further substantiate these findings we tested the affinity of triprolidine, a structural analog of acrivastine lacking the carboxylate moiety (Table III), for the Lys<sup>200</sup> → Ala receptor mutant. As expected, the affinity of this close structural analog was not reduced by the Lys<sup>200</sup> → Ala mutation (Fig. 6B and Table III). The Lys<sup>200</sup> residue is also involved in a specific interaction with the non-sedative, zwitterionic  $H_1$  antagonist d-cetirizine (Fig. 6C and Table III). Again, no effect of the Lys<sup>200</sup> → Ala mutation was found on the affinity of the analog meclozine, which does not contain a functional group that can interact with the Lys<sup>200</sup> residue in TM V (Fig. 6C and Table III).

#### DISCUSSION

More than 25 years after the initial hypothesis of Nauta *et al.* (30) of an interaction of the *trans*-aromatic ring of the  $H_1$  antagonist diphenhydramine with a Phe residue of an hypothetical  $\alpha$ -helical structure of the  $H_1$  receptor, we identified the aromatic amino acids Trp<sup>167</sup>, Phe<sup>433</sup>, and Phe<sup>436</sup> in the putative  $\alpha$ -helical TMs IV and VI of the  $H_1$  receptor as probable interaction points for the *trans*-aromatic ring of the  $H_1$  antagonists. Moreover, we found Lys<sup>200</sup> (TM V) to be a specific anchor point for the carboxylate moiety of the non-sedative, zwitterionic second generation  $H_1$  antagonists acrivastine and cetirizine.

The basis for the identification of these amino acids came from the docking of an  $H_1$  antagonistic pharmacophoric model (18) into a previously derived three-dimensional model of the  $H_1$  receptor (17). As a representative example of the first generation  $H_1$  antagonists, the rigid tricyclic cyproheptadine was allowed to interact with its protonated amine function with the highly conserved Asp<sup>116</sup> in TM III (7, 8). Several aromatic amino acid residues were predicted to interact with the aro-

matic rings of the  $H_1$  antagonist. Mutation of Trp<sup>174</sup> and Phe<sup>435</sup>, which were predicted to not be involved in ligand binding, had indeed no effect on the [<sup>3</sup>H]mepyramine binding. In contrast, for the mutant Trp<sup>167</sup> → Ala and Phe<sup>436</sup> → Ala receptors a dramatic loss of affinity of [<sup>3</sup>H]mepyramine was observed. Moreover, the Phe<sup>433</sup> → Ala mutation caused a total loss of  $H_1$  antagonist binding, despite membrane expression of the receptor protein and normal responsiveness toward histamine. Replacing Phe<sup>433</sup> and Phe<sup>436</sup> with the hydrophobic but aliphatic Met residue only slightly affected the binding of [<sup>3</sup>H]mepyramine, indicating that these two Phe residues in TMVI are most likely involved in a hydrophobic interaction with the  $H_1$  antagonist. Furthermore, a large reduction in the affinity and efficacy of histamine was observed for the Phe<sup>436</sup> mutants. This observation fits well with our recently developed model for the agonist interaction with the  $H_1$  receptor. In this model an interaction of Phe<sup>436</sup> with the imidazole ring of histamine is predicted.<sup>3</sup> Also for the Phe<sup>433</sup> → Met mutant lower affinity and efficacy are observed. In our model for the agonist-receptor interaction, a direct involvement of Phe<sup>433</sup> with the agonist binding is not predicted,<sup>3</sup> as substantiated by the full agonist activity at the Phe<sup>433</sup> → Ala mutant. Currently, we cannot explain the reduced agonist responses at the Phe<sup>433</sup> → Met mutant, although we can speculate that the flexible Met side chain prevents optimal agonist-receptor interaction by steric hindrance.

Replacing Trp<sup>167</sup> with either the aromatic Phe or the aliphatic hydrophobic Met did not allow high affinity [<sup>3</sup>H]mepyramine binding. Yet, the Trp<sup>167</sup> → Phe receptor mutant was able to functionally interact with histamine. These data suggest that Trp<sup>167</sup> is important for high affinity [<sup>3</sup>H]mepyramine binding but that hydrophobicity or aromaticity *per se* is not sufficient for a proper interaction. This could be explained if Trp<sup>167</sup> would be properly positioned in the binding crevice of the

<sup>3</sup> A. M. Ter Laak and R. Kühne, unpublished observations.

FIG. 6. Contribution of Lys<sup>200</sup> in TM V to the binding of the zwitterionic  $H_1$  antagonists acrivastine and cetirizine and their structural analogs triprolidine and meclozine to the  $H_1$  receptor. A, the binding of [ $^3$ H]mepyramine to the wild type, Lys<sup>200</sup> → Ala, Lys<sup>200</sup> → Met, and Lys<sup>200</sup> → Arg  $H_1$  receptor was displaced by acrivastine. The binding of [ $^3$ H]mepyramine to the wild type and Lys<sup>200</sup> → Ala  $H_1$  receptor was displaced by acrivastine and triprolidine (B) and cetirizine and meclozine (C). The data shown are from a representative example out of at least three independent experiments.

$H_1$  receptor by an interaction of its indole nitrogen with another (yet unidentified) amino acid of the  $H_1$  receptor.

Searching the GRAP mutant data base (31) for mutated residues at similar positions in other aminergic GPCRs, revealed considerable support for an important role of Trp<sup>167</sup>, Phe<sup>433</sup>, and Phe<sup>436</sup> in the binding of the *trans*-aromatic ring of the  $H_1$  antagonists. A polymorphism of the human  $\beta_2$  receptor (Thr<sup>164</sup> → Ile) at the position of Trp<sup>167</sup> in TM IV has been reported to alter ligand binding characteristics (32). Moreover, in the dopamine D<sub>2L</sub> (33), the 5HT<sub>2A</sub> (34), and the  $\beta_2$  receptor (35), a Phe residue in homologous position as Phe<sup>433</sup> has been implicated in hydrophobic or  $\pi$ - $\pi$  interactions with aromatic rings of receptor ligands. Similarly, in the muscarinic receptors an Asn residue is found at the same position as Phe<sup>433</sup>, and this Asn<sup>507</sup> plays a key role in the binding of various muscarinic antagonists to the m3 receptor (36). Finally, in both the dopamine D<sub>2L</sub> (37) and the  $\alpha_{1A}$  receptor (38) residues at a homologous position as Phe<sup>436</sup> are also involved in ligand binding.

Because of the perturbed protein expression of the Trp<sup>161</sup> →

Ala receptor, no conclusive decision could be made regarding its role in the binding of  $H_1$  antagonists. Mutation of Trp<sup>161</sup> with either Phe or Met is well allowed for high affinity [ $^3$ H]mepyramine binding or the interaction with histamine. A Trp<sup>192</sup> residue at homologous position of Trp<sup>161</sup> in the m3 receptor is important for both agonist and antagonist binding (39), suggesting that Trp<sup>161</sup> could be involved in an hydrophobic interaction with the *cis*-ring of the  $H_1$  antagonists as well. However, Trp<sup>161</sup> is 96% conserved throughout the GPCR family, suggesting a fundamental role in GPCR architecture (40). We can therefore not exclude the possibility that a hydrophobic amino acid at position 161 is simply essential to adopt a functional GPCR conformation.

Based on the results of the site-directed mutagenesis studies we concluded that the three-dimensional  $H_1$  receptor model had some predictive value for receptor-ligand interactions. To challenge our three-dimensional model the zwitterionic ligands acrivastine and d-cetirizine were fitted into the  $H_1$  receptor model. Both ligands contain a carboxylate moiety in either the *trans*-ring (acrivastine) or connected with a spacer to the amine-function (d-cetirizine). Modeling studies indicated a possible interaction of the negatively charged group with the amine of Lys<sup>200</sup> in TM V. The Lys<sup>200</sup> → Ala  $H_1$  receptor mutant shows normal binding of the classical  $H_1$  antagonist [ $^3$ H]mepyramine (10). Our present findings strongly suggest that Lys<sup>200</sup> is directly involved in the binding of the carboxylate group of acrivastine and d-cetirizine. The Lys<sup>200</sup> → Ala mutation results in a 30- (acrivastine) to 10-fold (d-cetirizine) loss of affinity of the zwitterionic antagonists, whereas the affinities of acrivastine and cetirizine analogs lacking the negatively charged carboxylate group, triprolidine and meclozine, respectively, are not affected by the Lys<sup>200</sup> → Ala mutation. The Lys<sup>200</sup> residue was also mutated to Met, which resembles the Lys residue sterically but does not contain a protonated amine function. As predicted, a huge reduction of the affinity of acrivastine was observed for the Lys<sup>200</sup> → Met receptor mutant. Moreover, a basic Arg residue is able to functionally replace Lys<sup>200</sup> → Ala as shown by the high affinity of acrivastine for the Lys<sup>200</sup> → Arg  $H_1$  receptor. These data provide strong evidence for the hypothesized ionic interaction between the carboxylate of acrivastine and the protonated amine function of Lys<sup>200</sup>. As observed previously for the interaction of histamine with the Lys<sup>200</sup> → Ala mutant receptor (10), histamine was less responsive at the Lys<sup>200</sup> → Met and Lys<sup>200</sup> → Arg  $H_1$  receptor as well. Whereas this is not surprising for the Met mutant (10), the observations with the Lys<sup>200</sup> → Arg  $H_1$  receptor indicate that the longer arginine side chain and the larger guanidinium group cannot optimally accommodate the imidazole ring of histamine. This observation will be important for the refinement of a three-dimensional model for the agonist-binding site.

In view of the emerging cardiotoxicity of several second generation  $H_1$  antagonists (41) and the current interest to combine potent nonsedative  $H_1$  antagonism with other anti-allergic activities (3), the identification of the role of Lys<sup>200</sup> will be of importance for the design of potent "third generation"  $H_1$  antagonists. The introduction of a carboxylate group in the structure of the  $H_1$  antagonists has by empirical approach been found to be a very effective way to limit central nervous system penetration and to derive nonsedative  $H_1$  antagonists like acrivastine (42) and cetirizine (43). Consequently, this structural element can also be found in other new  $H_1$  antagonists, *e.g.* carebastine, fexofenadine, KF-15766, KW-4679, levocabastine, and pibaxizine (for review see Ref. 3). Besides leading to favorable pharmacokinetics, the carboxylate group also discriminates the receptor binding of second generation  $H_1$  antagonists acrivastine and cetirizine from the first generation  $H_1$  antago-

TABLE III

Structural formulas and affinities of the  $H_1$  antagonists d-cetirizine, meclozine, acrivastine, and triprolidine for the wild type and  $Lys^{200} \rightarrow Ala$   $H_1$  receptor

The affinities of the  $H_1$  antagonists for the wild type and  $Lys^{200} \rightarrow Ala$  receptor mutant were determined in [ $^3H$ ]mepyramine displacement studies. Data shown are the means  $\pm$  S.E. of at least three independent experiments, each performed in triplicate.

general structure	R-group	$H_1$ antagonist	$K_i$ -value (nM)		ratio
			wild-type	$Lys^{200}Ala$	
		d-cetirizine	60 $\pm$ 8	492 $\pm$ 45	8.2
		meclozine	170 $\pm$ 35	108 $\pm$ 1	0.6
		acrivastine	10 $\pm$ 3	548 $\pm$ 52	54
	H	triprolidine	4 $\pm$ 0.5	2 $\pm$ 0.2	0.5

nists via its interaction with  $Lys^{200}$ . Because  $Lys^{200}$  is an unique residue for the  $H_1$  receptor, interaction of ligands with this residue via a carboxylate group will lead, in addition to limited brain penetration, probably also to good  $H_1$  receptor selectivity. For future design of non-sedative  $H_1$  antagonists the introduction of a carboxylate group capable of interacting with  $Lys^{200}$  could therefore be favorable.

In conclusion, our study shows that combining known interacting amino acids of the receptor (Asp<sup>116</sup>) with a pharmacophore for the  $H_1$  antagonist-binding site and verification by site-directed mutagenesis results in the identification of Trp<sup>167</sup>, Phe<sup>433</sup>, and Phe<sup>436</sup> in TM IV and VI as probable interaction points for the aromatic rings of  $H_1$  antagonists. Moreover, the use of the three-dimensional receptor model allowed the identification of  $Lys^{200}$  in TM V as specific anchor point for some non-sedative, zwitterionic  $H_1$  antagonists.
